## Regression concepts

In class exercise: Week 2

- 1. Suppose we use linear regression on a training dataset and get a sum of squared error equal to  $e_1$ . Using this model, we obtain a sum of squared error in the test set equal to  $e_2$ . We add some more new features (predictor variables) in the dataset and refit the model. Select the best option.
  - (a) The training error  $e_1$  always decreases or remains the same.
  - (b) The training error  $e_1$  always increases or remains the same.
  - (c) The test error  $e_2$  always decreases or remains the same.
  - (d) The test error  $e_2$  always increases or remains the same.
- 2. The statement, "the p-value is 0.001" is equivalent to the statement that "there is a 0.1% probability that the null hypothesis is true". True or False?
- 3. If you get a p-value of 0.1, it means that when the null hypothesis is true, a value of the test statistic as or more extreme than what was observed occurs in about 10% of all samples. True or False?
- 4. Suppose we solve a linear regression problem and obtain the optimal estimates  $\hat{\beta}_0, \dots, \hat{\beta}_p$ . Show that the average value of the residuals with these optimal estimates will be always 0.
- 5. Suppose a 95% confidence interval for the slope of a linear regression of y on x is given by  $-3.5 < \beta < -0.5$ . Then a two- sided test of the hypothesis  $H_0: \beta = -1$  would result in rejection of  $H_0$  at the 1% level of significance.
